ABSTRACT
Bacterial cellulose (BC) and its composites were synthesized from rice waste water (RWW) by addition of glycerol (G) and chitosan (Ch). The BC, BC-G and BC-G-Ch were characterized by several methods including Fourier Transform Infra Red (FTIR), Scanning Electron Microscopy (SEM), X-ray Diffraction (XRD), Thermogravimetric Analysis and Differential Thermal Analysis (TGA-DTA) and tensile tester. The data of FTIR, XRD, and TGA-DTA confirmed the presence of glycerol and chitosan in BC composites. The antibacterial activity of BC and its composites were tested against Staphylococcus aureus ATCC 25923 by clear zone method. The experimental data shows that BC-G-Ch exhibits a higher antibacterial activity in comparison to BC and BC-G.

Keywords: Acetobacterxylinum, antibacterial activity, bacterial cellulose, chitosan, glycerol.

INTRODUCTION
Cellulose is an abundant natural polymer material which is produced naturally by many plants, algae, and also an assortment of bacteria [1]. Agrobacterium, Rhizobium, Pseudomonas, Sarcina, and Acetobacter are some genera of bacteria which produce cellulose [2]. The BC which is produced by Acetobacter xylinum, shows significant difference from cellulose obtained from plants. A network of pure cellulose is free lignin and hemicellulose which can be obtained in a culture medium as a pellicle composed of fibers with a size less than 100 nm. These cellulose fibers are composed of fine threads nanoscale [1,2]. Commercial product of cellulose can be used as an ingredient for making tires, membranes of headphones, special paper, textile, and biomedical applications as a temporary skin substitute [2] derived from nanometer-sized cellulose with unique properties.

The purity of bacterial cellulose is higher than that of cellulose of plants, and it does not contain lignin and hemicellulose. BC is obtained through a simple process, no further purification process to remove contaminants and unwanted polymer, and therefore, it retains a greater degree of polymerization [3]. The BC presents in high cristallinity. Cellulose I and cellulose II are two crystalline forms of cellulose. A. xylinum in static culture and most of the plants produce cellulose I. Cellulose I and cellulose II are composed of β-1,4-glucan chains in different structure. Cellulose I exhibits parallel structure, whereas cellulose II exhibits random and antiparallel structure, and also hydrogen bonds, so that the cellulose II shows a higher thermodinamic stability than cellulose I [1, 4]. The BC is also used as dietary fiber and as a binding or thickening agent [1]. Crystallinity and the amount of acrfic that can be grafted into the cellulose structure will affect the ability of BC to absorb water. Biomedical material has been studied from a cellulose phosphate membrane. Similarly, bone regeneration applications and osteo integration have been studied from phosphorylated cellulose [2].

The BC exhibits a unique structure and mechanical properties in comparison with higher plant cellulose. A surface area per unit mass of the BC fiber is high, as a result of its diameter of 20-100 nm. The combined properties of cellulose has a large surface area with highly hydrophilic property, and the resulting material can be applied in various fields with a very wide area, particularly in biomedical needs and biotechnology [5]. It is important to design an efficient production of BC by aeration and agitation method, so it can be produced effectively with good quality and economical for industrial-scale production [6].

Bacterial cellulose can be prepared from household waste, such as RWW. The RWW contains starch, protein, minerals, and vitamin B, which can be used as a source of nutrients for Acetobacter xylinum in synthesizing bacterial cellulose. Vitamin B in RWW will help Acetobacter xylinum to grow in the bad environment. Glucose in RWW is used by bacteria in fermentation process, while protein in RWW can be used as a source of nitrogen, and sucrose was added in the substrate of RWW as a source of carbon which is needed by Acetobacter xylinum. Urea can be used as an additional source of nitrogen also.

Medical applications of BC primarily aim to prevent aninfestation by pathogenic microorganisms. Addition of chitosanon BC is aimed to provide antimicrobial properties to cellulose. Chitosanis a glucosamine biopolymer produced from deacetylation of chitin. Recent studies claimed that a bacterial growth can be inhibited effectively by chitosan [7, 8]. Chitosanhas a positively charged amine groups that will bind to the negatively charged amine groups on the surface of microorganisms [8]. Institute of Chemical Fibers (ICWH) Poland has synthesized BC composite by introducing chitosan on BC [8].
According to The National Nosocomial Infection Surveillance System (NNIs), *Staphylococcus aureus* is one of the most common pathogens in the wound. Wei *et al.* [9] stated that *Staphylococcus aureus* is one of gram-positive bacteria generally found on the contaminated wounds. Due to that reason, we focused on preparation of BC and its composites from RWW on addition with glycerol and chitosan and its application as antibacterial materials against *Staphylococcus aureus*.

**MATERIALS AND METHODS**

Rice was purchased from the traditional market in Yogyakarta. The RWW was obtained from the first wash of rice by aquadest. Sucrose, urea, glycerol, and acetic acid were purchasedas commercial products and used as they were without any further purification. Nutrient Agar (NA) and Nutrient Broth (NB) were purchased from Oxoid. *Acetobacter xylinum* and chitosan (DD = 73.78%) were purchased from Bratachem, Yogyakarta and *Staphylococcus aureus* was obtained from collection of Faculty of Medicine, Universitas Gadjah Mada.

**Preparation of bacterial cellulose and its composites**

Rice wastewater was prepared by washing a kilogram of rice by a liter of aquadest. The mixture was filtered and the filtrate was collected in a container. The BC-G-Ch was prepared as the following. Twenty grams of rice was purchased from the traditional market in Yogyakarta. The RWW was obtained from the first wash of rice by aquadest. Sucrose, urea, glycerol, and acetic acid were purchasedas commercial products and used as they were without any further purification. Nutrient Agar (NA) and Nutrient Broth (NB) were purchased from Oxoid. *Acetobacter xylinum* and chitosan (DD = 73.78%) were purchased from Bratachem, Yogyakarta and *Staphylococcus aureus* was obtained from collection of Faculty of Medicine, Universitas Gadjah Mada.

The dry mass of BC and BC-G composite was found much higher in comparison with BC-G-Ch composites. The BC and BC-G composites are able to absorb more water than the BC-G-Ch composite. The BC has mushy and watery texture. The adding chitosan on structure of BC will decrease its water absorption. These results correspond to the results reported by Sadikin et al.[11]. Chitosan is able to enter into the pores and inner surface of BC so that it blocks water to enter [12-14]. It is possible that hydrogen bonding between chitosan and the -OH group of BC might occur so that the water cannot bind -OH group.

Figure 1 shows that for the spectrum of BC-G-Ch, a wide band appears in the region 3400 cm⁻¹ which indicates the presence of –NH₂ of chitosan and –OH of BC [15]. The band which appears around 1570 cm⁻¹ for the three spectra indicates the presence of aromatic rings. The peak around 1558.48 cm⁻¹ which appears on the spectrum of BC-G-Ch should correspond to amino groups of chitosan [7]. The typical stretching of C=O group of chitosan around 1635.64 cm⁻¹ can be observed clearly in the spectrum of BC-G-Ch. The peaks of -NH₂ and C=O groups in this spectrum of the BC-G-Ch indicate that chitosan has been successfully attached on the structure of BC.

Table 2 shows absorbance of –OH and –NH in the BC, BC-G and BC-G-Ch. The introduction of glycerol and chitosan in the structure of BC causes reducing the absorbance of the -OH group. The decreasing absorbance of -OH group may be caused by the formation of hydrogen bonding between cellulose and glycerol (chitosan). This will support the decreasing in percentage of elongation of bacterial cellulose as well as increasing thermal stability of bacterial cellulose-glycerol-chitosan. The presence of chitosan will broaden the band of -OH group on the spectrum of BC at around 3400cm⁻¹.

The broadening of this band indicates an overlapping between -OH and -NH₂ groups due to the hydrogen bond [7]. Based on Figure 2, the presence of the bands at 635.64 cm⁻¹ and 1566.20 cm⁻¹ associated with the stretching of C=O (Amide I) and bending of -NH (Amide II), respectively, suggests that the amide groups of chitin are not deacetylated perfectly [7].

Morphological images

Figure 2 shows morphological image of BC, BC-G composite, and BC-G-Ch. Bacterial cellulose is composed by fibrilar organization where each fibril is comprised of a thousand of single linear glucan chain forming a net-like structure. Through SEM images it was noticed that a large deposition of glycerol over the BC surface covered the fibril. The cross section image shows bulk microfibrils denoting that glycerol can also penetrate through the surface pores of BC. However, the third image shows the difference of BC before and after introducing of chitosan. It is evident that chitosan was able to coat the entire surface of BC.
Mechanical properties and crystallinity

As shown in Table-3 the tensile strength of BC and BC-G were found to be 22.48 MPa and 15.60 MPa, respectively. Decreasing in tensile strength was due to the presence of glycerol as a plasticizer agent that made material less rigid. Due to its lower rigidity, BC-G exhibits lower tensile strength and higher elongation in comparison to BC. Tensile strength of BC and BC-G were different. The percentage of elongation of BC-G was found 28.12% while in the BC it was only 22.18%. It is evident that the addition of glycerol as a plasticizer reduces the tensile strength but increases elongation of bacterial cellulose. Rechia 	extit{et al.} [16] studied about increasing the glycerol concentration in the film which reduced elasticity modulus and tensile strength, exhibiting a plasticizing effect.

However many researches such as Zhong and Xia [12] who tested the chemical and physical properties of a film that was added with glycerol as plasticizer agent showed that this can cause a decrease in tensile strength. This decreasing was due to reduced intermolecular interactions between cellulose and glycerol.

The tensile strength of BC-G-Ch was found lower than that of BC but higher than that of BC-G (Table 3). The lower tensile strength of BC-G-Ch might be caused by chitosan which is amorphous, whereas the cellulose itself is a crystal. A strong structural material due to its higher crystallinity naturally is resilient to higher pressure than the irregular structure of materials and provided lots of space around it. The increasing of amorphous phase in the material which has a high crystallinity will reduce its strength at break of material [15]. The addition of chitosan decreased the elongation of composites significantly, from 28.12% for BC-G to 8.01% for BC-G-Ch. The use of cornstarch films can cause intermolecular bonds, forming hydrogen bonding. This bond increased tensile strength but decreased elongation [16].

The existence of rigid structure in the polymer chain will make it difficult to move when it is pulled so that elongation will decline [12]. A decline in the crystallinity of BC-G-Ch in comparison with BC was observed. A decrease in the crystallinity showed the addition of amorphous phase in the structure of BC. Chitosan was able to reduce the crystallinity of BC due its amorphous nature. The BC has a high crystallinity, which related to high mechanical properties of BC [3, 13]. Zhijiang[13] studied that the addition of chitosan on BC with the concentration range from 12 to 45 wt % decreased its tensile strength from 130 MPa to 54 MPa while the percentage of elongation dropped from 12% to 6.8%.

Figure-3 shows the XRD patterns of BC, BC-G, and BC-G-Ch. Diffraction peak at 15° is associated with the phases of cellulose 1α (1001α, 1101β, and 0101β), nevertheless peak at 22.5° reveals the phases planes of cellulose 1β (2001β)[2]. The BC shows diffraction peaks at above 22.5°. For X-Ray diffractogram of BC-G and BC-G-Ch at above 30°, the broadening peak corresponding to amorphous phase was observed. It indicates that the addition of glycerol and chitosan can change crystalline region in BC.
Figure-3. The X-Ray diffractogram of (a) BC; (b) BC-G; and (c) BC-G-Ch.

The presence of glycerol and chitosan caused a decreasing in the degree of crystallinity of BC. The degree of crystallinity of BC, BC-G, and BC-G-Ch was calculated and found to be 73.65%, 47%, and 50.15% respectively. Chitosan and glycerol are amorphous materials, whereas cellulose is a crystalline. The existence of the amorphous nature in BC caused deterioration of its crystallinity. The degree of crystallinity affected the mechanical properties of BC [16]. The decreasing degree of crystallinity can decrease tensile strength. The BC-G-Ch exhibits higher tensile strength than the BC-G, due to its higher degree of crystallinity. Besides, the addition of chitosan will increase the tensile strength caused by the formation of hydrogen bonding between cellulose and chitosan so that the rigidity of the composite increased.

Thermal properties

Thermogram in Figure-4 shows endothermic peak as the release of water molecules on heating [2]. BC-G-Ch released water molecule ate elevated temperature in comparison to BC and BC-G because the cellulose pores was blocked with chitosan, so that water molecules was trapped inside of cellulose structure. Glycerol and chitosan led to an increase in the amount of water molecules, consequently the endothermic peak of BC-G-Ch and BC-G occurred at higher temperatures than BC.
The peaks profiles suggest that a crystallization and/or phase transition preceded a thermal degradation. Crystallization and transition of glycerol and chitosan were an exothermic process continued thermal degradation of cellulose. Fragmentation process of carbonyl and carboxylic bonds in anhydrous glucose units giving carbon or carbon monoxide is partial pyrolysis, and it can be observed as a broad exothermic peak [2]. Glass transition of BC was observed at 270 °C and crystallization of its was observed at 330°C [2]. The BC and its composites were degradated at above 400°C.

As shown in Figure-5, two significant losses of weight were observed at the temperature range of 37-100°C and 200-350°C. The first loss might be associated with dehydration of membrane. Water bound through hydrogen bonding and physically adsorbed can be detached at lower temperature of the first stage. The second loss was due to thermal degradation, and the BC-G exhibits the highest thermal stability. The first mass loss, going from 30 to 100°C for membrane dehydration.

Based on Figure-5, BC-G exhibits the lowest loss in mass in comparison to the other two. The BC-G-Ch composite indicates the highest loss in mass in comparison to the other two. The lowering thermal stability of BC-G-Ch in comparison to BC might be due to differences in the polymerization of the cellulose. Polymerization of cellulose without glycerol and chitosan forms linear polymers whereas when to the cellulose polymer is added the glycerol and chitosan it produces branching polymers. Chemical bonds in the linear polymer β-1,4-glycosidic are covalent, while in the branching polymer, hydrogen bonds are present. The covalent bond is stronger than the
hydrogen bonds so that the linear polymer is more difficult to decompose than the branching polymers [17]. Another possibility, because glycerol and chitosan is evaporated of polymers. It is also possible that the branching polymer is easily evaporated on the second stage. Composite of glycerol-polymer will evaporate at 200°C temperature [14]. The BC-G exhibits higher thermal stability in comparison to the BC. This can be caused by the presence of hydrogen bonding between -OH group in cellulose chain and –OH group in glycerol chain.

Antibacterial activity

Table-4 shows that the diameter of inhibition zone of BC was found the lowest in its composites. The presence of glycerol and chitosan on the structure of BC can increase its antibacterial activity. Chitosan can increase the permeability of the outer and inner membrane which can eventually damage the cell membranes of bacteria and followed by releasing of bacterial cell contents. This damage was due to the electrostatic interaction between -NH$_3^+$ groups of chitosan and phosphoryl group in the phospholipid bilayer in bacterial cell membranes [18]. Chitosan can interact with teichoic acid and forms an impermeable layer that prevents the entry of important molecules for the organism.

The cell wall structure of the *Staphylococcus aureus* is thick, which is useful for protection from antibacterial agents such as antibiotics, toxins, chemicals and degradative enzymes. Peptidoglycan of *Staphylococcus aureus* is composed of teichoic acid, a polysaccharide which is linked with other sugars by phosphodiester bonds. Teichoic acid contains -COOH and phosphate groups, thus providing a negative charge on the surface of bacterial cells. Antibacterial activity of BC-G is caused by a covalent interaction between -OH groups in glycerol and COOH or -COO- group in the membranes of bacterial cell. It was confirmed by previous authors [19, 20] that glycerol with higher concentrations exhibits antibacterial activity and can function as a good storage media for the cadaver allograft skin. Glycerol is safe to use in conserving the cadaver skin for several weeks at room temperature due to its antibacterial activity [19, 20]. This study showed that all samples have antimicrobial activity against *Staphylococcus aureus*. Inhibition zone which occurs in cellulose is consistent with coordinate covalent bond, wherein the reducing of cellulose will react with a positive charge existing in the cell wall of the bacteria *Staphylococcus aureus*.

CONCLUSIONS

The addition of chitosan during preparation steps affected the physical properties of bacterial cellulose, the intensity of the functional groups, mechanical properties, the thermal stability, and its antibacterial activity. The tensile strength and crystallinity of bacterial celluloses decreased after the addition of chitosan. However, the addition of chitosan can increase intensity of functional group and antibacterial activity. The addition of glycerol can decrease the intensity of the functional groups, tensile strength, and crystallinity of composites but it can increase thermal stability, elongation, and antibacterial activity of bacterial cellulose.
