ABSTRACT
The article presents the results of studies on synthesis and hydration of aluminate clinkers and cements containing $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}\text{S}_4$ phase. Influence of calcium sulfate and iron oxide additives on thermal transformations during $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}\text{S}_4$ synthesis was determined. A method for calculating composition of three-component mixture for, which takes into account $\text{MgO}$ and $\text{SiO}_2$ presence in raw materials is proposed. The calculation method makes it possible to optimize phase composition of clinker due to directional choice of the modulus of basicity, silica and magnesia modules. Aluminate clinker was synthesized from raw mixes with different modules values. Dependence of properties of aluminate cements on values of the modules and content of clinker’s phases was revealed. Composition of hydrated aluminate cement with the content of $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}\text{S}_4$ phase is presented. There was marked strength stability of cement stone of long-lasting hardening.

Keywords: aluminate clinker, calcium magnesium silicoaluminate, clinker formation, cement hydration.

1. INTRODUCTION
Special cements have unique properties and are able to meet the needs of various branches of construction. Of particular practical interest are aluminate cements. High rate of hardening of aluminate cements makes it possible to refuse heat treatment during hardening of concrete [1-3].

Recently, there has been a shortage of alumina-containing raw materials, so the possibility of replacing traditional raw materials with industrial waste is being investigated [4]. To obtain clinker cements raw materials that contain minerals based on silicon, magnesium and iron are used [4-12]. In raw mixtures of complex composition, calcium magnesium silicoaluminate $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}\text{S}_4$ is formed, which is also called magnesian pleochroite or Q phase [13-16]. Information about synthesis and properties of $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}\text{S}_4$ are few. An understanding of $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}\text{S}_4$ effect on the properties of aluminate cements is required.

Objective: to study the processes of synthesis and hardening of aluminate cements containing $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}\text{S}_4$ phase.

2. MATERIALS AND METHODS OF INVESTIGATION
For synthesis of the studied phase, a mixture of stoichiometric composition of chemical reagents was used. To obtain clinkers, mixtures of dolomitic limestone, substandard bauxite, and magnetite ore wastes were prepared. Sub-conditioned bauxite contains: %: $\text{SiO}_2$ - 12; $\text{Al}_2\text{O}_3$ - 50; $\text{Fe}_2\text{O}_3$ - 5; $\text{CaO}$ - 1; $\text{SO}_3$ - 4; $\text{R}_2\text{O}$ - 0.5; others - 2.5; loss on ignition - 25. Chemical composition of magnetite ores waste, %: $\text{SiO}_2$ - 40; $\text{Al}_2\text{O}_3$ - 12; $\text{Fe}_2\text{O}_3$ - 14; $\text{CaO}$ - 13; $\text{MgO}$ - 5; S - 7; $\text{R}_2\text{O}$ - 4; loss on ignition - 5. The samples of raw mix were burned in the temperature range of 1150 - 1350 $^\circ$C.

Strength properties of cement were determined on samples of size 20x20x20 mm solidified in water. Phase $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}\text{S}_4$ was identified using infrared spectroscopy and microscopy. Composition of clinker and cement stone was analyzed using X - ray phase method. The phase composition of the raw mixture, burnt at temperatures of 800 - 1350 $^\circ$C, was determined using general purpose X - ray diffractometer, type DRON - 3M. The diffractometer is equipped with a BSV - 24 type X - ray tube with CuK $\alpha$ - radiation. The diffractograms were processed using difWin program.

3. RESULTS AND DISCUSSIONS
3.1 Synthesis of $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}\text{S}_4$ phase
Study of clinker formation in polymineral mixtures is difficult because of variety of processes and compounds. Therefore, a stoichiometric mixture designed for preparation of magnesium calcium silicoaluminate of $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}$ was used for the research. The raw material mixture was prepared from chemically pure reagents of $\text{CaCO}_3$ (based on 39.83 % of $\text{CaO}$), $\text{Al}_2\text{O}_3$ (48.28 %), $\text{SiO}_2$ (7.12 %), $\text{MgO}$ (4.77 %). The raw mix was burned at temperatures of 1150 - 1300 $^\circ$C. According to the data of diffractometric analysis, it was established that intensive formation of $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}$ occurs at a temperature of 1250 - 1350 $^\circ$C (Figure-1).

Comparison of infrared spectrum of $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}$ phase (Figure-2) with the reference spectra of various calcium aluminates reveals similarities of $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}$ and CA structures. This confirms the presence of absorption bands in the area of (650 - 900) cm $^{-1}$, belonging to alumino-oxygen tetrahedral units. A distinctive feature of $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}$ IR spectrum is the band of (1000 - 1040) cm $^{-1}$ - the absorption region for $\text{SiO}_2$ tetrahedral units.

Microscopic examination of clinker in immersion preparations confirmed $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}$ phase presence. Crystal-optic $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}$ characteristics: $N_g$ = 1.673; $N_p$ = 1.669. $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}$ phase crystallizes as prismatic $\text{Ca}_6\text{Al}_4\text{Mg}_4\text{Si}_4\text{O}_{26}$ crystals (Figure-3).
3.2 Effect of additives on C₆A₄MS phase formation

Formation of C₆A₄MS in the presence of calcium sulfate, which is introduced for modified aluminate clinkers [17-20], was studied. CaSO₄ was added to stoichiometric mixture designed for synthesis of C₆A₄MS in the amount of 5 wt. % over 100 % (Figure-4). When CaSO₄ is added to the mixture, part of calcium aluminates is converted to calcium sulfoaluminate 3(CA)CaSO₄. The amount of gehlenite C₂AS decreases as a result of the following reaction:

\[ 3C_2AS + 3C + CaSO_4 \rightarrow 3(CA)CaSO_4 + 3C_2S. \]  

A significant proportion of dicalcium silicate C₂S is converted to calcium silicosulfate 2(C₂S)CaSO₄ and does not participate in C₆A₄MS formation.

Therefore, coexistence of 3(CA)CaSO₄ and C₆A₄MS is possible in aluminate clinkers with initial and predominant formation of calcium sulfoaluminate.

In alumina-containing raw materials combinations of impurities of silicon, magnesium and iron are not uncommon. The effect of Fe₂O₃ on C₆A₄MS formation phase was studied. Phase changes were revealed during burning of the raw mix, calculated to produce C₆A₄MS, with addition of 10 wt. % of Fe₂O₃ in excess of 100% (Figure-5).

With introduction of Fe₂O₃, intermediate phases CF, C₂F, C₂MF are formed by reducing the amount of calcium aluminates; C₆A₄MS synthesis is intensified, including with participation of C₂MF, C₆A₄F:

\[ 4CA + C_2S + C_2MF \rightarrow C_6A_4MS + C_2F, \]  

\[ C_2MF + 3A + 3C + C_2AS \rightarrow C_6A_4MS + CF, \]
The content of $C_6A_4MS$ in iron-containing clinker is reduced by almost 20%. Along with the $C_6A_4MS$ phase, $C_6A_2F$, $C_2AS$, which are not involved in synthesis of $C_6A_4MS$ is present in the calcined mixture. Clinker formation in the iron-containing mixture is completed at 1250 - 1280 °C, with increase in temperature the clinker melts. Melting of clinker is accompanied by decay of $C_6A_4MS$ with release of $CA$.

### 3.3 Method of calculating the composition of raw mixes for aluminite clinkers

Lime stones and bauxites with different content of $SiO_2$ and $MgO$, waste products of magnetite ores were used for clinkers synthesis with the content of $C_6A_4MS$ phase.

A method for calculating the composition of raw mixes for aluminite clinkers production using modules $a$, $n$, and $m$ has been developed.

The modulus of basicity expresses the degree of saturation of alumina with calcium oxide and characterizes the ratio of $CaO$: $Al_2O_3$:

$$a = \frac{C - 1.87S - 1.05F - 0.70SO_4 - 0.55A}{0.55A},$$  \hspace{1cm} (5)$$

where $C$, $S$, $F$, $SO_4$, $A$ – content of oxides in the raw mix or clinker, %:

1.87 - is the ratio of $CaO$ mass to the mass of $SiO_2$ in $C_2S$;

1.05 - is the ratio of $CaO$ mass to the mass of $Fe_2O_3$ in $C_3F$;

0.70 - is the ratio of $CaO$ mass to the mass of $SO_4$ in $CaSO_4$;

0.55 - is the ratio of $CaO$ mass to the mass of $Al_2O_3$ in $CA$.

For values of $a \geq 1$ in the clinker, formation of inert $C_2AS$ is excluded.

The silica module $n$ expresses proportion of $SiO_2$ bound in $C_6A_4MS$, and the ratio between aluminate and silicate phases of the clinker as follows:

$$n = \frac{0.147A}{S},$$  \hspace{1cm} (6)$$

where 0.147 - is the ratio of $SiO_2$ to $Al_2O_3$ mass in $C_6A_4MS$.

The magnesia modulus $m$ characterizes the ratio of $MgO$ required for binding $Al_2O_3$ in $C_6A_4MS$, to the total concentration of $MgO$:

$$m = \frac{0.099A}{M},$$  \hspace{1cm} (7)$$

where 0.099 - is the ratio of $MgO$ mass to the mass of $Al_2O_3$ in $C_6A_4MS$.

To minimize the content of $C_2S$ and limit of free $MgO$ proportion in the clinker, it is advisable to increase the values of the modules: $n \geq 0.5$; $m \geq 0.5$.

Raw mixes were burnt at a temperature of 1300 - 1320 °C until complete binding of calcium oxide. Analysis of diffractograms shown in Figure-6 indicates a complex composition of clinkers. In the highly basic clinker 1C,
along with 3(CA) CaSO₄ and C₃A is present. Increase in silica in the mixture for clinker 2C causes the appearance of C₂S belite. In the low-base clinker 3C, C₂AS gehlenite dominates, it contains C₂S belit and small amounts of 3(CA) CaSO₄ and C₃A are preserved. Synthesis of clinkers with a given content of magnesium silicoaluminate calcium indicates the validity of calculations of raw mix composition, made by the proposed method.

The phase composition of clinkers affects hardening of cements (Table-1). Cements 2C and 3C contain silica phases and harden slowly. Cement 3C includes gehlenite and is characterized by low strength during all test periods.

Aluminate clinkers were synthesized, differing in the value of silica module (Table 2). Raw mixes were burned at temperatures of 1300 - 1370 °C.

Strength properties of cements depend on the content of aluminate phases and achieve the highest performance under increased values of silica module (n ≥ 1). Presence of calcium monoaluminate in K - 1.5 clinker provides accelerated hardening in the early period. Total MgO content in clinkers of K – 1.5; K - 1.0 and K - 0.5 exceeds the recommended limit and, accordingly, is equal to, wt.%: 5.1; 5.4; 6.1. However, the main part of magnesium oxide is bound in calcium magnesium silicoaluminate. Periclase concentration is low (Table-2) and does not cause destructive changes in the cement stone during hardening.

The proposed method of calculating the composition of three-component mixtures is focused on formation of C₆A₄MS phase in the clinker. Formation of magnesium silicoaluminate is not the main goal, but serves as a way to maximize conversion of inert compounds into the active phase. In addition, each 1 % of MgO is able to bind 1.49 % of SiO₂ and convert 6.77 % of inert gehlenite into the active phase of C₆A₄MS. On the other hand, 0.5% of MgO is involved in the formation of every 10% of magnesium calcium silicoaluminate. This allows you to increase the level of permissible total MgO content in the clinker.

### 3.4 Hydration of cement with a high content of C₆A₄MS phase

The processes of hydration and hardening of cement with a high content of C₆A₄MS were investigated. Cement was obtained from clinker with modules: a = 1.1; n = 0.98; m = 1.01 (Table-3). Phase composition of clinker, wt. % is: C₆A₄MS - 55; C₃A - 12; C₁₂A₇ - 11; 3(CA)CaSO₄ - 15; C₁₄AF - 7.

Cement is characterized by moderate setting speed, intensive hardening in the first three days, stable development of strength and maintaining of high strength values while long-range hardening (Table-3).

The nature of cement hardening reflects characteristics of C₆A₄MS hydration phase. Analysis of diffractograms of cement in the early periods of hydration (Figure-7) indicates the initial formation of C₄AH₁₃ (d = 0.804 nm), CAH₁₀(subsequent formation (d = 1.43; 0.716 nm) and C₂AH₈ (d = 1.08 nm). On the radiograph of a stone at the age of 1 day, reflections of ettringite are noted (d = 0.98; 0.49 nm), formed during hydration of calcium sulfoaluminate.

Stable increase in cement stone strength during long-term hardening is associated with increased stability of hexagonal calcium hydroaluminates, low rate of their recrystallization. CAH₁₀ (d = 1.43; 0.720; 0.375; 0.255 nm) was found in cement hardened for 10 years; its content exceeds the amount of C₃AH₆ (d = 0.514; 0.336; 0.278; 0.228; 0.202 nm) and AH₃ (d = 0.482; 0.440; 0.240 nm).
Duration of hexagonal calcium hydroaluminates existence is achieved by stabilizing effect of hydrated magnesium-containing and silicon-containing ions formed during hydrolysis of initial C₆Å₄MS phase and incorporated into the matrix structure.

4. CONCLUSIONS

Calcium magnesium silicoaluminate C₆Å₄MS is a preferred magnesium-containing and silica-containing phase of aluminate clinkers. When C₆Å₄MS is formed, mutual «neutralization» of SiO₂ and MgO impurities undesirable for aluminate clinkers occurs. Formation of C₆Å₄MS is accompanied by minimization or exclusion of
C₂AS, C₆S and MgO phases, characterized by low hydration activity.

The combined presence of C₆A₆MS and 3(CA) CaSO₃ in aluminate clinkers was established during initial and predominant formation of calcium sulfoaluminate. Formation of C₆A₆MS is promoted by increased concentration of Fe₂O₃.

High hydraulic activity of cements containing calcium magnesium silicoaluminate indicates reasonability of C₆A₆MS phase presence in the aluminate clinker.

The developed method for calculating of mixtures’ composition makes it possible to optimize phase composition of aluminate clinker using the specified values of basicity modulus of (a > 1), silica module (n > 0.5) and magnesian module (m > 0.5). Possibility of directed influence on the formation and properties of aluminate clinkers contributes to expansion of raw materials resources for cement production.
